## ABSTRACT

Few studies have been conducted on the social and behavioral aspects of marine recreational anglers. It has generally been assumed that anglers represent a homogeneous group when using catch data obtained from recreational anglers. Anglers were interviewed at boat ramps, wade/bank areas and commercial lighted piers in each of seven Texas bay systems during 1974 through 1976. Anglers were asked their country, state (if in the United States) and county (if in Texas) of residence. Differences in patterns of geographic origin and distance of residence from each bay system were determined for anglers interviewed during each season at each type of fishing platform (strata) in each bay system. Most (94.2%) of the anglers resided in Texas with 1.4% from states adjacent to Texas, 4.1% from other states in the United States and 0.4% from two foreign countries. Anglers in each bay system except the Aransas Bay and the lower Laguna Madre systems generally exhibited this same pattern of geographic origin. In these two systems the geographic origin of recreational anglers changed dramatically between seasons and fishing strata. Out-of-state residents comprised a large proportion (about 20-50%) of the wade/bank and lighted pier anglers in the winter and spring in the Aransas Bay system and in the winter in the lower Laguna Madre system. These "winter Texans" also comprised over 40% of the winter boat anglers in the Aransas Bay system. The localization of "winter Texans" to the south Texas area may have been related to available facilities, population adjacent to each bay system and climate. Patterns of anglers' geographic origin were not consistent among bay systems. The pattern for zone of origin was also dependent on either season, fishing strata or both. Anglers traveled from the Galveston area to fish in other bays, but the reverse did not occur. Distance, population, facilities and climate probably affected each angler's selection of the bay system in which to fish.

## INTRODUCTION

The importance of obtaining information on fisheries resource users, especially recreational anglers, has increased dramatically in recent years. It is essential that the characteristics of anglers be determined for the development of effective management strategies. The concept of optimum sustainable yield requires that harvest limits be a function of some biologically allowable catch as modified by pertinent sociologic, economic and political factors. Few studies have been conducted on the social and behavioral aspects of marine recreational anglers and it is assumed that they represent a homogenous group (Bryan 1976). It seems unlikely that the diversity of fishing experiences available in Texas' coastal zone would be utilized by one group homogeneous in their social, economic, and political characteristics. It is imperative, therefore, that the constituency of marine recreational anglers be defined to establish a known population from which statistically reliable and meaningful socioeconomic data can be obtained for establishing levels of optimum sustainable yield.

Data on the characteristics of recreational anglers using Texas bays were almost completely non-existent until 1974 when the Coastal Fisheries Branch of the Texas Parks and Wildlife Department initiated a survey to estimate the minimum harvest of finfish by recreational anglers. Demographic data were also collected, and a cursory analysis of the data was provided in Heffernan et al. (1977) and Breuer et al. (1977). This study examines the geographic origins of recreational anglers fishing in each of seven major Texas bay systems. The origin, with respect to distance from the "target" bay system for anglers using three types of fishing platforms (strata) during each season in each bay system was determined and compared.

## MATERIALS AND METHODS

Anglers in the Galveston, San Antonio, Aransas and upper Laguna Madre Bay systems were surveyed during September 1974 through August 1975; those in the Matagorda, Corpus Christi and lower Laguna Madre Bay systems during September 1975 through August 1976 (Heffernan et al. 1977, Breuer et al. 1977). Anglers using three fishing strata--boat ramps, wade/bank areas and commercial lighted piers--were interviewed on 104 different days in each bay system during the sample year. Eight randomly selected days (4 weekdays and 4 weekend days) each were spent sampling randomly selected lighted piers and wade/bank areas per season; randomly selected boat ramps were sampled on 10 days (4 weekdays and 6 weekend days). Each season consisted of 3 months; September, October and November comprised the fall; December, January and February the winter; March, April and May the spring; and June, July and August made up the summer. Anglers leaving boat ramps and wade/bank areas were interviewed between 6:00 a.m. and 2:00 p.m. or between 2:00 p.m. and 10:00 p.m.; those at lighted piers between 2:00 p.m. and 10:00 p.m. or between 10:00 p.m. and 6:00 a.m. The time period was randomly selected for each day. One angler (the apparent "leader") from each party was interviewed about the harvest and asked

his country, state (if in the United States) and county (if in Texas) of residence.

The percent of anglers interviewed in each bay system who resided in Texas, states adjacent to Texas, all other states in the United States (U.S.) and foreign countries was calculated for each season and each fishing strata. Significant ( $P < 0.01$ ) differences in the pattern of geographic origin of interviewed anglers between season and fishing strata within each bay system were determined using the log likelihood ratio test (Sokal and Rohlf 1969). The test is similar to  $\chi^2$  but involves the transformation of the raw data to natural logarithms prior to the calculation of the test statistic  $G$ . Prior to the analysis, the number of anglers in each geographic origin category interviewed during each season at boat ramps was multiplied by 0.8 to adjust for differences in the number of sampling days at each strata. For each bay system where geographic origin was independent of season and strata, all data were used to calculate one percentage value for each origin category in that bay system. Differences in origin pattern among bay systems were determined using the log likelihood ratio test when origin was independent of season and fishing strata.

A series of concentric zones was constructed around each bay system (Fig. 1). Texas counties included in each zone surrounding each bay system were determined by constructing arcs around each bay system on a Texas highway map (Anonymous 1975). The center of each arc surrounding a bay system was the midpoint of the Gulfward boundary of that bay system. Arcs with radii of 100, 200, 400, 600, 800, 1000 and 1200 km enclosed zones 1, 2, 3, 4, 5, 6 and 7, respectively. The boundary of each arc was modified to coincide with county lines. Counties with at least 50% of their area within a zone were included in that zone (Appendix A). Total population in each zone (Appendix B) was determined by summing the 1970 populations of those counties within each zone (Anonymous 1979). Significant ( $P < 0.01$ ) differences in the pattern of zone of residence within Texas for interviewed anglers between season and fishing strata within each bay system were determined using the log likelihood ratio test.

## RESULTS

Texas residents comprised the majority of the recreational anglers using Texas bays. Most (94.2%) of the 7,478 recreational anglers who were interviewed during the study resided in Texas with 1.4% from states adjacent to Texas and 4.1% from other states in the U.S. Thirty residents (0.4%) of two foreign countries, Mexico (27 anglers) and Canada (3 anglers), were interviewed. At least 46% of the anglers interviewed in each bay system at each strata during each season were Texas residents, with the percentage in this category usually approximating 100% (Table 1). In the Galveston and San Antonio Bay systems, >98% of the anglers interviewed at each strata during each season were Texas residents; the percentage of anglers residing in each geographic category was independent of season and strata (Table 2). In addition, the percentage of anglers within each geographic origin category was the same in Galveston and San Antonio Bay systems ( $G = 2.376$ , d.f. = 3,  $P > 0.05$ ). For these two systems combined, 99.5% of all fishermen interviewed

were Texas residents, 0.1% were from states adjacent to Texas, and 0.4% were from all other states in the U.S. and 0.0% were from foreign countries.

In each of the other five bay systems, the pattern of geographic origin varied with either season, strata or both (Table 2). In the Corpus Christi Bay system, the percentage of anglers within each geographic category was dependent on season only. Texas residents comprised 91.1% of the fall and winter anglers and 95.1% and 98.8% of the spring and summer fishermen, respectively. In the upper Laguna Madre system, the percentage of anglers within each geographic category was dependent on strata only. Texas residents comprised 99.3% of the boat anglers, 94.1% of the wade/bank anglers and 93.1% of the lighted pier anglers. In the Matagorda Bay, Aransas Bay and lower Laguna Madre systems, the percentage of anglers within each geographic category was dependent on both season and strata. In the Matagorda Bay system, Texas residents comprised >90% of the anglers in each season and strata except in the winter at wade/bank areas (86.1%) and lighted piers (46.2%). In the Aransas Bay and lower Laguna Madre systems, the geographic origins of recreational fishermen changed dramatically between seasons and fishing strata (Table 1). The proportion of out-of-country residents exceeded 3% only in the lower Laguna Madre. In this system, out-of-country residents comprised 2% of all anglers and were encountered at boat ramps in the summer; wade/bank areas in the winter, spring and summer; and lighted piers in each season.

The percentage of interviewed anglers residing in each distance zone within Texas was not consistent among bay systems (Fig. 2). The pattern for zone of origin depicted in Figure 2 was the same ( $P>0.01$ ) in all seasons and at all fishing strata in the San Antonio Bay, Corpus Christi Bay and upper Laguna Madre systems (Table 3). In the Galveston and Matagorda Bay systems, the pattern of origin was independent of season but not fishing strata; in the lower Laguna Madre system the pattern of origin was independent of strata but not season (Fig. 3). In the Aransas Bay system, the pattern of origin was not independent of season or strata (Fig. 4).

The distribution of the state's 11,196,730 population around each bay system varied substantially among bay systems. There was no apparent relationship between the zone of origin of anglers and each zone's population for any of the bay systems (Fig. 3).

## DISCUSSION

Texas residents comprised over 80% of the anglers interviewed in each bay system during each season at each strata except in the winter in the Matagorda Bay, Aransas Bay and lower Laguna Madre systems and in the spring in the Aransas Bay system. The low percentage of Texas residents interviewed in the Matagorda Bay system at lighted piers during the winter (46.2%) may have been due to the small number of anglers interviewed (13). The use of the Aransas Bay and lower Laguna Madre system by out-of-state anglers in the winter probably reflects the annual migration of residents of "northern" states who spend their winters in south Texas. These so called "winter Texans" are apparently centralized in the Rockport and Aransas Pass area (located on the Aransas Bay system) and the Rio Grande Valley (adjacent to the lower Laguna

Madre system) perhaps because of the availability of facilities (mobile trailer parks, motels and winter homes) or the warm climate. In addition, the "winter Texans" using the Aransas Bay area apparently stay longer (through spring) and use more fishing strata (all three) than those in the lower Laguna Madre. Perhaps they occur in greater numbers or they fish more extensively in the Aransas Bay system than in the lower Laguna Madre. Unfortunately, no data are available on the number of "winter Texans" annually visiting each of these two areas or on their fishing habits. However, as seasonal residents of these two areas, "winter Texans" comprise a substantial portion of the recreational anglers using two of the seven bay systems. If these anglers have different expectations of their fishing experience from those of Texas residents, then the management strategies imposed by the fisheries agency should consider those different expectations.

Generally, Texas residents fishing in Texas bays lived within 100 km of the bay in which they fished, with the proportion coming from each distance zone decreasing as distance increased. In the San Antonio and Aransas Bay systems, however, 40-50% of the Texas anglers resided in zone 3 where about 45% of the state's population also resided. Anglers selection of the bay system in which to fish is probably a function of distance and population. However, these are not the only factors involved in the selection process. The population immediately adjacent to a bay system may act to reduce the number of anglers travelling to that system. Over 99% of the Texas anglers interviewed in the Galveston Bay system resided within 100 km of the system. Anglers did not travel over about 100 km to fish in the Galveston Bay system. However, anglers from the Galveston area travelled to all other Texas bays, including the most remote--the lower Laguna Madre. Season and available fishing platforms in each strata also apparently influenced the selection process; the anglers' residence was dependent on one or both of these factors in four of the seven bay systems.

The patterns of geographic origins of recreational anglers presented in this study were determined for wade, bank and private boat strata during the day and for pier strata during the night. Those using bank areas and private boats during the night and those using piers during the day were not surveyed. Anglers who store their boats on the water, fish from private boats not launched at public boat ramps or fish from charter or party boats were not surveyed. In addition, only the apparent "leader" of each party was interviewed. The residence of anglers in each party may not have been the same as that of the party's "leader." Therefore, care should be taken when extrapolating results presented herein to the total population of recreational anglers.
