PROJECT NUMBER: 88

PROJECT TITLE: Assessment of Golden-cheeked Warbler Habitat Characteristics on Texas Parks & Wildlife Department Lands for Use in Hill Country Outreach Programs

PROJECT OBJECTIVES:

1. To analyze and interpret existing data on the locations of golden-cheeked warbler sightings on state lands and the vegetation, soils, topography, and other characteristics of the habitat associated with these locations.
2. To develop outreach materials (brochure with photographs and illustrations, reproducible handouts for land managers, maps) to interpret results and offer improved guidance on management of marginal habitats.

Date

Executive Summary

The purpose of this study was to link existing GIS data, representing golden-cheeked warbler siting localities, with vegetation surveys conducted at these locations. A total of 549 warbler sitings on 11 Texas Parks and Wildlife State Parks and State Natural Areas were included. These parks are located in 6 of the 8 Recovery Regions as identified by the USFWS (1992), Golden-Cheeked Warbler Recovery Plan. Results of analysis of vegetation data indicated that:

- (i) canopy height ranged from approximately 4 to 7.5 meters
- (ii) coefficient of variation of canopy height ranged from approximately 11% to 49%
- (iii) Ashe juniper represented 37% to 70% of the total vegetation observed in transects
- (iv) composition of dominant woody plant species were similar to those observed elsewhere, except three additional species (pecan, black willow, and silktassel) were commonly associated with warblers at three different parks.

An appendix is included containing maps of the state parks with golden-cheeked warbler locations and associated tabular data describing canopy structure and abundance of dominant woody plant species.

Significant Deviations:

Under Part 1. of the project objectives (above), *spatial* analysis of golden-cheeked warbler locality data was not completed. Low spatial accuracy (\pm 50 m) of the existing GIS point data made subsequent analysis of slope, aspect, hydrography and other GIS data layers problematic. Spatial accuracy of warbler GIS data was compromised by a combination of DOD "selective availability" and lack of post-processing GPS differential correction. Part 2. of this project (the development of outreach materials) was dependant, in part, on spatial analysis in Part 1. Part 2. was not initiated. Total Section 6 funds spent on this project were \$1,330.29.

I. Need.

There continues to be a need for information concerning the nature of breeding habitat used by golden-cheeked warblers in the counties where they occur in central Texas. Guidance for landowners is still needed for what has been termed "marginal habitat" or habitat types that "may be used" by warblers and which might be suitable areas for safe harbor, habitat conservation planning, landowner incentive programs, and other forms of habitat restoration work. Biologists and other resource professionals with Texas Parks and Wildlife, US Fish and Wildlife, and various conservation organizations are faced with providing guidance to landowners concerning effective management and restoration activities. State Park managers face similar decisions with regard to management of golden-cheeked warbler habitat on public lands. Several studies have described the characteristics of high quality woodland habitat (Beardmore, 1994; Pulich, 1976; Wahl et al., 1990), but few have described the characteristics of lower quality habitat types which may be used by warblers. In this study, we link vegetation data to approximately five hundred sitings of golden-cheeked warblers on eleven Texas State Parks and Natural Areas. The goal of this study was to learn more about vegetative characteristics associated with golden-cheeked warblers in what has been viewed as "less-optimal" habitat to help identify suitable lands for conservation planning and management.

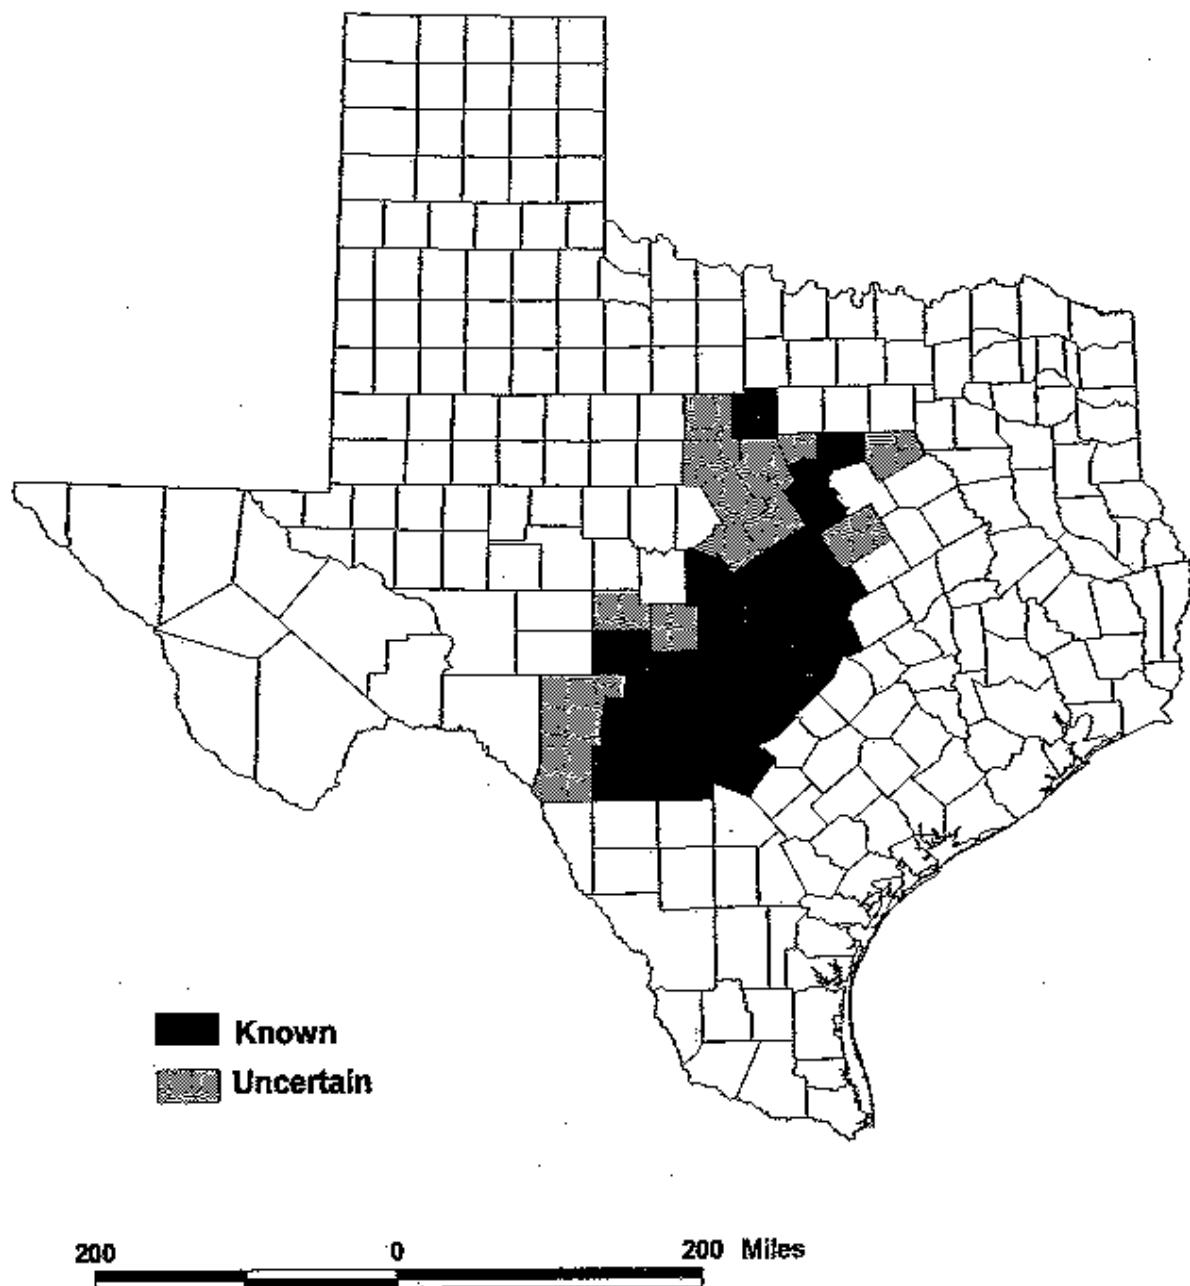

II. Background

Literature on the breeding and wintering ranges of the golden-cheeked warbler has been reviewed by Ladd and Gass (1999). The breeding range is confined to central Texas. Distribution extends across portions the Edwards Plateau, Lampasas Cut Plain and Llano Uplift regions of central Texas (Figure 1). Winter range includes the highlands of southern Mexico, Guatemala, Honduras and Nicaragua. The recovery plan for this species divides golden-cheeked warbler breeding distribution into eight recovery regions (USFWS, 1992). State parks with warblers are located in six of the eight regions (Regions 3 and 7 are not included) (Figure 2).

Vegetation associated with golden-cheeked warbler breeding habitat has been described as dense forest and woodlands (USFWS, 1992). Woody habitat contains a dominant component of Ashe juniper along with several deciduous species including oaks, elms, Texas ash, Texas persimmon, hackberry and others (Beardmore, 1994; Ladd, 1985; Pulich, 1976; USFWS, 1992; Wahl et al., 1990). The sloughed bark of older Ashe juniper (> ca. 20 years) is a critical component for golden-cheeked warbler nesting materials (Kroll, 1980; Gass, 1996).

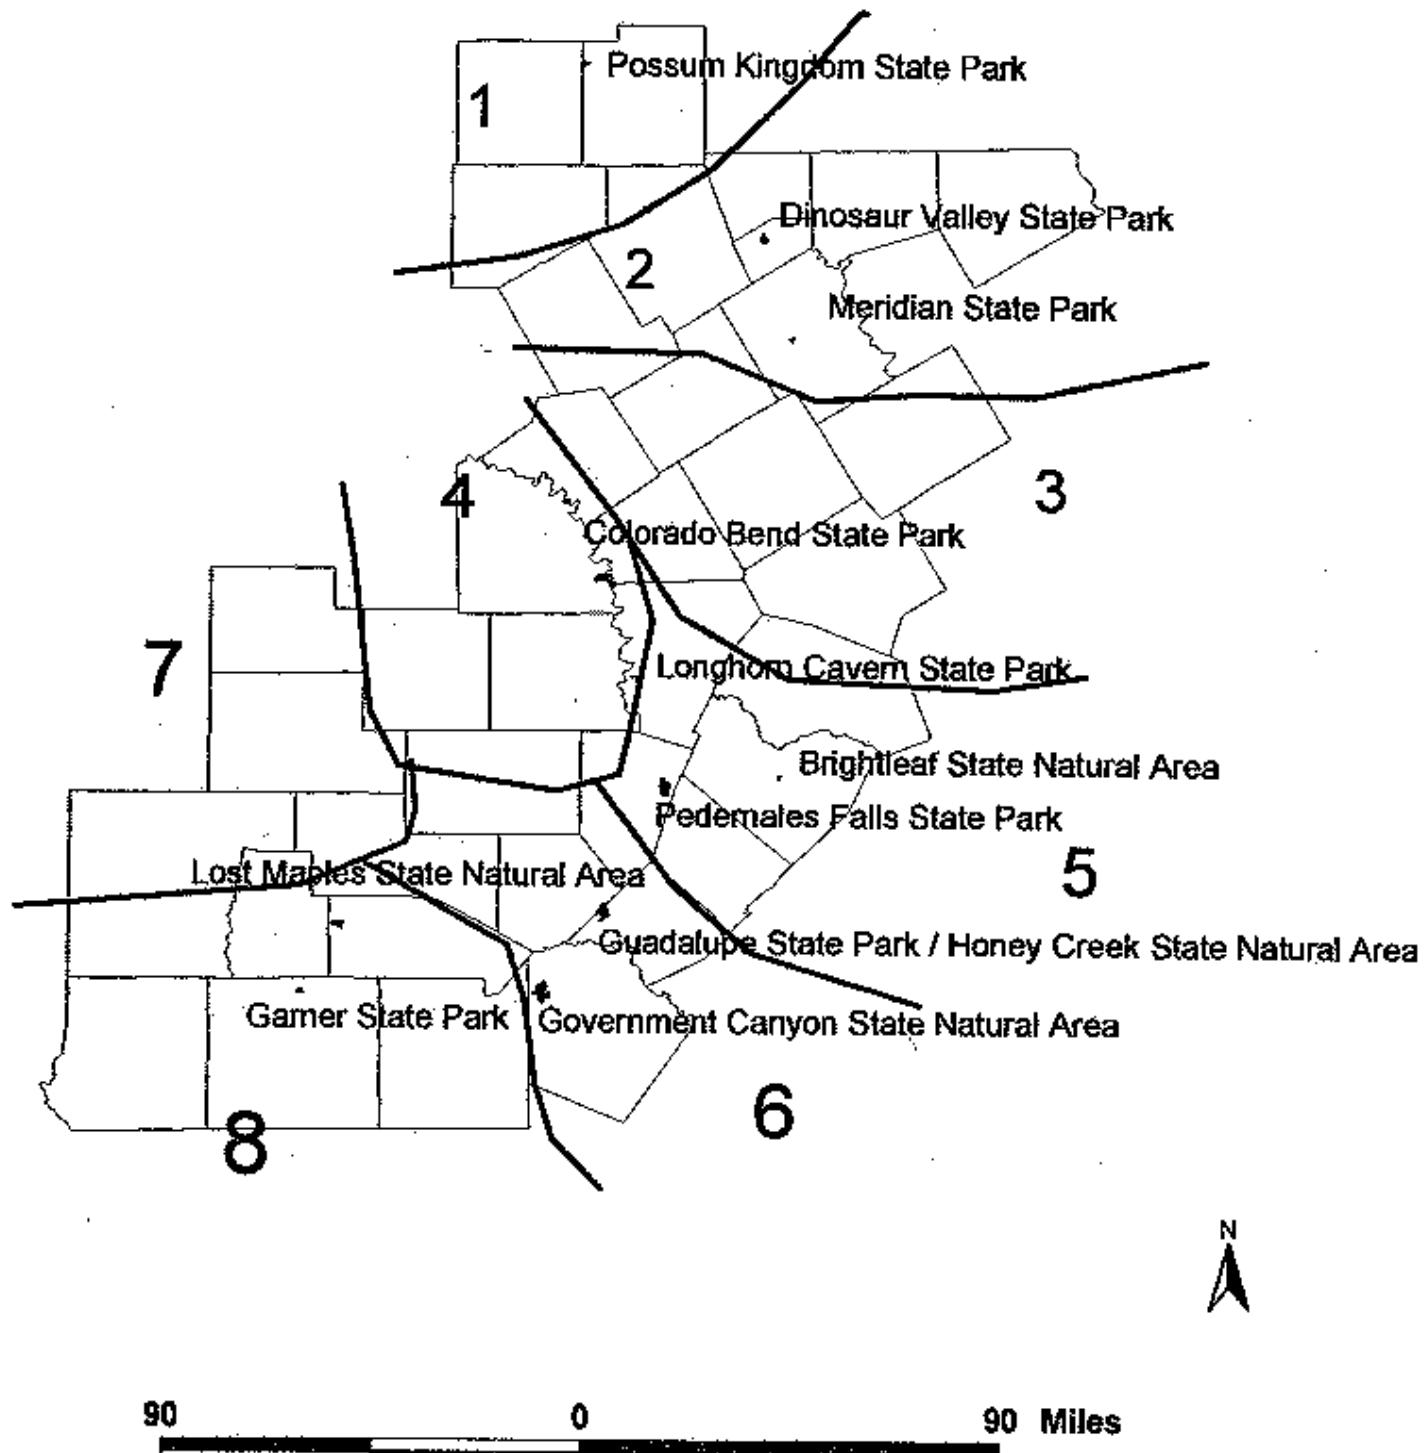

Breeding habitat requirements and habitat restoration objectives were addressed in a workshop arranged by the USFWS (1996). They characterized golden-cheeked warbler breeding habitat as vegetation with a canopy cover greater than 50% with a mixture of mature Ashe juniper and broad-leaf trees at least 10 ft. tall. This habitat is typically (though not always) found on shallow limestone soils and associated steep slopes. Discussion of patch size, the role of habitat "edge" and habitat fragmentation in the context of golden-cheeked warbler habitat has been considerable. Wahl et al. (1990) observed in all but one of their study sites ($N = 17$), warblers were detected in surveys of contiguous patches greater than 50 ha. USFWS (1992) questioned earlier studies in the interpretation of golden-cheeked warblers as an "edge" species. Engels (1995) observed that patterns of urbanization tend to create woodlands that are speckled by urban development rather than creating islands of discrete habitat. Coldren (1998) found

Figure 1 -- Breeding Range

Based on Ladd and Gass, 1999.

Figure 2 -- Recovery Regions for Golden-cheeked Warbler (from USFWS, 1992).

evidence of higher reproductive success towards the forest interior, but also noted that agriculture and grasslands were more commonly found adjacent to occupied habitat patches while medium-density and high-density residential development were more often found adjacent to unoccupied patches. USFWS (1996) recommended maintaining mature Ashe juniper/broad leaf woodlands with greater than 50% canopy and that areas with greater than 90% young Ashe juniper should be selectively thinned to allow regeneration of oaks and other broad-leaved trees. They suggest that managers allow the natural re-establishment of junipers on sites with broad-leaved trees where junipers have been selectively removed, in order to achieve the necessary mix of Ashe juniper and deciduous woodland species required by golden-cheeked warblers.

III. Study Objectives

1. To analyze and interpret existing data on the locations of golden-cheeked warbler sightings on state lands and the vegetation, soils, topography, and other characteristics of the habitat associated with these locations.
2. To develop outreach materials (brochure with photographs and illustrations, reproducible handouts for land managers, maps) to interpret results and offer improved guidance on management of marginal habitats.

IV. Approach

Existing GIS data representing Golden-cheeked warbler sightings were acquired from state park surveys. A total of 549 warbler sightings for 11 state parks and natural areas were acquired as Arc/Info point coverages and loaded into ArcView version 3.1 GIS software (ESRI, Inc.). Spatial accuracy of GPS data was low (+/- 50 meters) due to a combination of DOD "selective availability" and lack of GPS differential correction. Therefore, subsequent spatial analysis of these data is omitted in the current study and our analysis will focus on the characteristics of the vegetation associated with warbler breeding habitat.

Vegetation transect data were acquired on TPW lands by Texas Department of Transportation staff as part of a cooperative interagency project. Transects were designed following the methods of Mills et al. (1991). A 20-meter transect was established adjacent to each of the warbler sighting points. Vegetation type and volume were measured every 2 m. along the transect. A second 20-meter transect was established perpendicular to the first, yielding a total of 20 measurements for each warbler point location. Vegetation volume analysis will be reported elsewhere (Cal Newnam, pers. comm.).

ArcView attribute tables were created from the vegetation transect data using a combination of Excel spreadsheets and Perl programs (Wall et al., 1996). Attribute tables were then joined to warbler location point layers for each park. Each GIS point location contains the following non-spatial attribute information: mean canopy height, standard deviation of canopy height, coefficient of variation of canopy height, and number of "hits" of each woody species along vegetation transects. Numbers of hits were based on presence/absence of a given species at each sampling point along the transect pair (range: 0 to 20). We analyzed vegetation transect data to describe (i) mean and distribution of canopy height across state parks and state natural areas, (ii) coefficient of variation of canopy height for each state park to assess variability of vegetative structure, (iii) composition of dominant woody species, and (iv) percent Ashe juniper at each location.

Figure 3: Canopy Height at Golden-cheeked Warbler Locations

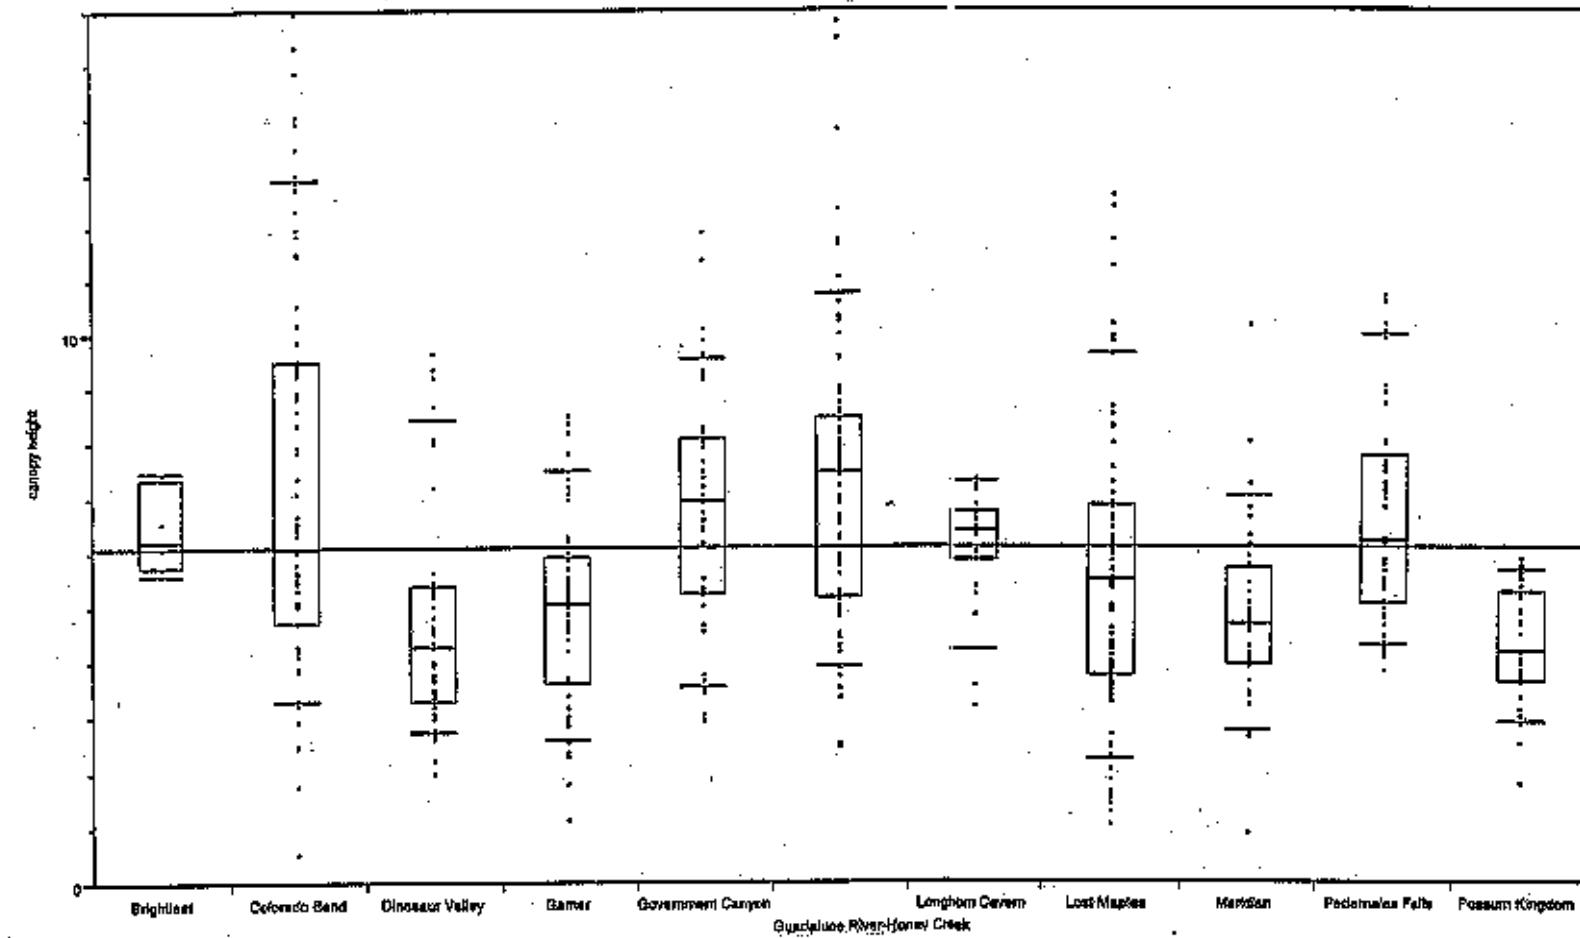

Table 1 – Woody plants recorded on vegetation transects associated with Golden-cheeked Warbler locality data from Texas state parks and natural areas (data provided by Texas Department of Transportation). Scientific and common names are based on Hatch et al. (1990). Genus/species codes are used in Table 2 and also in the ArcView tables.

V. Results

Quantitative data for woody plant species observed in vegetation transects near golden-cheeked warbler sitings are summarized in the ArcView attribute tables (Appendix A, Table 1 describes species codes used in Appendix A and in Table 2).

Canopy height (measured as the maximum height at each sample point) varied considerably across state parks and state natural areas (Figure 3 – Kruskal-Wallis Test, $P < 0.0001$, $N = 549$). The overall mean canopy height across all parks was 6.097 meters. State park average canopy heights from lowest to highest were: Possum Kingdom (mean = 4.297, $N = 31$), Dinosaur Valley (mean = 4.754, $N = 43$), Meridian (mean = 4.863, $N = 40$), Garner (mean = 4.976, $N = 50$), Lost Maples (mean = 5.582, $N = 86$), Longhorn Cavern (mean = 6.133, $N = 24$), Brightleaf (mean = 6.443, $N = 7$), Pedernales Falls (mean = 6.636, $N = 54$), Government Canyon (mean = 6.806, $N = 52$), Colorado Bend (mean = 7.266, $N = 76$), Guadalupe River / Honey Creek (mean = 7.320, $N = 86$).

Coefficient of variation (CV) measures the relative amounts of variation in populations with different means (Sokal and Rohlf, 1981). It is the standard deviation expressed as a percentage of the mean. CV of canopy height was calculated for park to assess variation of vegetation structure. Parks ranked from lowest to highest in terms of percent variation were Brightleaf (11.47%), Longhorn Cavern (17.18%), Possum Kingdom (24.60%), Pedernales Falls (28.48%), Government Canyon (31.38%), Meridian (34.04%), Garner (35.37%), Guadalupe River / Honey Creek (37.94%), Dinosaur Valley (43.11%), Lost Maples (46.37%), and Colorado Bend (49.03%).

The most common woody plant species found along vegetation transects at all eleven parks was Ashe juniper (*Juniperus ashei*) (Table 2). This was followed, in order of decreasing frequency, by various oak species (*Quercus fusiformis*, *Q. glaucoidea*, *Q. sinuata*, *Q. texana*, *Q. stellata*), cedar elm (*Ulmus crassifolia*), silktassel (*Garrya ovata*), Texas ash (*Fraxinus texensis*), Texas persimmon (*Diospyros texana*), black willow (*Salix nigra*), pecan (*Carya illinioensis*), walnut (*Juglans spp.*) and blackcherry (*Prunus serotina*).

The overall percentage of Ashe juniper in relation to all woody species along vegetation transects averaged 52.7% across all parks (Table 2). State parks, in order of increasing percentage of Ashe juniper, were as follows: Colorado Bend (38.5%), Government Canyon (38%), Lost Maples (43.8%), Guadalupe River / Honey Creek (44.3%), Brightleaf (51.4%), Dinosaur Valley (54.1%), Pedernales Falls (58.3%), Garner (59.0%), and Possum Kingdom and Longhorn Cavern tied for highest (69.4%).

VI. Discussion

Results from this study indicate that golden-cheeked warblers were most often seen in vegetation ranging from approximately 4 to 7.5 meters in height in Texas state parks and state natural areas. This is somewhat higher than the minimum recommendation for managing warbler habitat in USFWS (1996) which is 3.05 meters (10 feet). Mean canopy height was highly variable between state parks. Similarly, variation in canopy height differed highly between parks with CV values comparatively small (< 20%) in some parks (Brightleaf and

Table 2 – Dominant woody plants associated with Golden-cheeked warblers on Texas state parks and state natural areas; Dominant species represent the five most common woody plants based on “hits” along vegetation transects (see methods for details); Percent Ashe juniper is the total number of Ashe juniper “hits” along transect divided by the total number of “hits” for all species (see methods for details). Genus/species codes are given in Table 1. Recovery Regions are based on U.S. Fish and Wildlife Service (1992).

<u>Recov. Reg.</u>	<u>Park</u>	<u>Dominant woody species</u>	<u>Ja %</u>

Longhorn Cavern) but large (> 40%) in other parks (Dinosaur Valley, Lost Maples, and Colorado Bend).

No clear association or trend could be established between mean canopy height and coefficient of variation. Some parks had high levels of variation yet had low average canopy heights (Dinosaur Valley, Garner, Lost Maples) while others had relatively low amounts of variation with high average heights (Brightleaf, Pedernales Falls, Government Canyon). Other parks had both high canopies and high levels of canopy variation (Colorado Bend, and Guadalupe River / Honey Creek). Still others had moderate to high mean heights with low variation or visa versa (Longhorn Cavern, Meridian). Only one state park had both low canopy height and low variation (Possum Kingdom). Higher and therefore more mature Ashe juniper / oak woodlands tend to be more favorable habitat for the golden-cheeked warbler. Similarly, increase in variation in canopy height, might be expected as woodlands mature and their species composition diversifies. Unfortunately, variation in canopy height might also arise from disturbance impacts such as clearing, overbrowsing, and introduction of exotic species. While canopy height is likely to be a good indicator of habitat quality, the link between canopy variation and habitat quality is unclear.

Dominant Woody Plants

Each of the dominant woody plant species found along warbler site transects in state parks (Table 2) is mentioned in Pulich (1976) except pecan (*Carya illinioensis*), black willow (*Salix nigra*) and silktassel (*Garrya ovata*). Pecan was commonly associated with golden-cheeked warbler sites at Colorado Bend State Park. Black willow was common found along transects at Garner State Park. And silktassel was commonly found at Brightleaf State Natural Area. None of three species was dominant at other parks. None of three species is mentioned in the Status Review (Wahl et al., 1990) or the Recovery Plan (USFWS, 1992). Pecan is a component of deciduous forests and woodlands along major rivers (TNHP, 1992) such as the Colorado River. It probably contributes to the foraging area for warblers at Colorado Bend State Park. Silktassel occurs throughout the rocky limestone hills of central Texas (Vines, 1984). Again, it probably also serves as a foraging substrate at Brightleaf State Natural Area. Black willow, which is found throughout stream beds and rivers of central and east Texas, may play a similar role at Garner State Park. It is important to note that, while these dominant woody species were very common in the vicinity of warbler siting locations, these are observations drawn from vegetation transects and not from direct observations of the birds themselves.

Percent Ashe juniper

USFWS (1996) habitat management recommendations include the selective thinning of junipers on sites dominated by 90% or more Ashe juniper. The purpose is to promote regeneration of oaks and other broad-leaved trees. Results from this study support this recommendation. Results indicate that warblers occur on parks dominated by approximately 37% to 70% Ashe juniper. None of the parks with golden-cheeked warblers exceeded this 90% Ashe juniper level. Similar results are reported elsewhere (Beardmore, 1994).

Conclusions

As has been noted in earlier studies, there exists a suite of vegetation characteristics that are critical for determining habitat suitability for golden-cheek warbler breeding habitat. Results from this study support minimum canopy height recommendations by USFWS (1996). Dominant woody plant species observed in this study were similar to those reported elsewhere, except three additional species (pecan, black willow, and silktassel) were found to be commonly associated with warbler locality data at three specific parks. Percent Ashe juniper associated with golden-cheeked warbler sitings were similar to values reported elsewhere.

V. Acknowledgements

The following persons from Texas Department of Transportation participated in the vegetation characterization study: Doug Booher, Cal Newnam, George Oliver, Ben Archer, Dave Sugeno, Dan Ricks, Daniel Thompson, Kate Newcomb, Amy Sugeno, Marianne Bailey, Cory Chism, and Karen Couch. Cal Newnam also provided valuable suggestions in the development of this project. Base coverages were provided by Michelle Valek of Texas Parks and Wildlife, Parks Division.
