**ABSTRACT**

_Carissa macrocarpa_ (Eckl.) A. DC. is documented as occurring outside of cultivation in Texas. Several colonies were found growing on shell middens in Nueces County. It is suspected that seeds were dispersed from landscape plantings in the Corpus Christi area. _Carissa macrocarpa_ has moderate invasive potential along the Texas coast.

**KEY WORDS:** Apocynaceae, _Carissa macrocarpa_, Texas, naturalized.

_Carissa macrocarpa_ (Eckl.) A. DC. (Apocynaceae), commonly known as Natal plum, was recently documented as naturalizing in Nueces County, Texas. The species has not been previously reported outside of cultivation in Texas (Correll & Johnson 1970; Hatch 1990; Jones et al. 1997; Turner et al. 2003).

_Carissa macrocarpa_ is native to the coastal region of Natal, South Africa. It was introduced into the United States in 1886 by the horticulturist Theodore L. Meade. In 1903, David Fairchild of the Office of Foreign Seed and Plant Introduction of the United States Department of Agriculture imported a large quantity of seeds from the Botanical Garden at Durban, South Africa. Several thousand seedlings were raised at the then Plant Introduction Garden at Miami and distributed for testing in Florida, the Gulf states and California. Extensive effort was devoted to following up on the fate of the plants in different climatic zones. _Carissa macrocarpa_ was introduced into Hawaii in 1905 and over the next few years was extensively distributed throughout the islands. It was planted in the Bahamas in 1913. It first fruited in the Philippines in 1924 and is grown to a limited extent in India and East Africa. The species is valued mainly as a protective hedge, while the fruit is edible and suitable for fruit salads, cakes, puddings, ice cream, pies, and tarts. The summary information above on _Carissa macrocarpa_ is taken from Morton (1987).

_Carissa macrocarpa_ (Fig. 1) was found growing on shell middens in Nueces County. It is suspected that seeds were dispersed from landscape plantings, possibly by birds, in the Corpus Christi, Texas area. Three colonies (averaging 3 x 3 meters) were documented at this site. These colonies are reproducing vegetatively with branches rooting low to the ground. Elsewhere in the USA, _Carissa macrocarpa_ is known to be naturalized only in Florida, where Wunderlin and Hansen (2010) report that it occurs in seven counties.
Shell middens (or shell mounds) in the mid-Gulf coast of Texas are located on the back side of dunes and are composed of shells (clams, oysters, whelks) with inter-dispersed sand. The middens support an assemblage of calciphilic plants. The dominant flora of the shell middens includes *Opuntia stricta*, *Dalea emarginata*, *Heterotheca subaxillaris*, *Indigofera miniata*, and *Yucca treculeana*. Other common associates include *Aphanostephus skirrhobasis*, *Chamaecrista fasciculata*, *Chamaesyce* sp., *Chloris* sp., *Croton punctatus*, *Cyperus* sp., *Dichanthelium* sp., *Distichlis spicata*, *Gaillardia pulchella*, *Ibervillea lindheimeri*, *Orobanche ludoviciana*, *Rhynchosia americana*, *Oenothera drummondii*, *Paspalum* sp., *Plantago hookeriana*, *Portulaca pilosa*, and *Sporobolus pyramidatus*. See Slater and Kincaid (2004) for a discussion of the botany of shell middens in Florida.

Fig. 1. *Carissa macrocarpa* (Natal plum) in Nueces County, Texas

*Carissa macrocarpa* (Figs 1, 2) is a vigorous, spreading woody shrub with abundant, gummy-white sap. It may reach a height of 4.5–5.5 m and an equal breadth. The branches are armed with stout, double pronged thorns of up to 5 cm long. Leaves are evergreen, opposite, broad-ovate, 2.5–5 cm long, dark green, glossy, and leathery. Flowers are sweetly fragrant, white, 5-lobed with tubes to 5 cm and are borne singly or few together at the tips of branches. The fruits are ovoid to spheroid, to 6.25 cm long and 4 cm wide. Upon ripening, the tender smooth skin turns a bright magenta-red. The fruit contains 6–16 small, flat, brown seeds.
