ABSTRACT

Texas bays were stocked with over 94 million fish eggs, fry, and fingerlings from October 1975 through December 1985. Red drum (Sciaenops ocellatus) was the major species released (over 89 million fish). However, striped bass (Morone saxatilis), spotted seatrout (Cynoscion nebulosus), black drum (Pogonias cromis), and snook (Centropomus undecimalis) were also stocked. All stockings were intended to revitalize historic or enhance existing fisheries. At least one species was stocked in each of the nine major bay systems.

INTRODUCTION

Stocking saltwater fishes into Texas bays has become an integral part of the Texas Parks and Wildlife Department's (TPWD) management program to revitalize historic fisheries and speed recovery of overfished stocks. Most effort has focused on red drum (Sciaenops ocellatus) and striped bass (Morone saxatilis). Over 56 million red drum eggs, fry, and fingerlings were stocked during 1975-1982 (Matlock 1984), and 494,000 striped bass fingerlings were stocked during 1975-1977 (Matlock et al. 1984). Stockings of spotted seatrout (Cynoscion nebulosus) and black drum (Pogonias cromis) have occurred since 1983. The objective of this report is to provide a reference document of stocking activities necessary for evaluating stocking in salt water by updating Matlock (1984).

MATERIALS AND METHODS

Fish reared by TPWD at the Perry R. Bass Marine Fisheries Research Station during experimental culture studies or at the John Wilson Marine Fish Hatchery for stocking purposes were stocked into Texas bays. Data for 1983, 1984, and 1985 were taken directly from TPWD data sheets completed at the time of each stocking and summarized by species, life stage (eggs, fry and fingerlings), calendar year, bay system and stocking site (Appendix A). The total length (mm) range and mean were included for fingerlings, if available. Data for 1975 through 1982 were from Matlock (1984) and Matlock et al. (1984), and corrected by updating the data base. Information on red drum eggs released by Dr. Connie Arnold from The University of Texas Marine Science Institute at Port Aransas, was from Matlock (1984).

RESULTS AND DISCUSSION

Over 94 million fish eggs, fry, and fingerlings were stocked into Texas bays from October 1975 through December 1985. Matagorda, San Antonio, and Corpus Christi Bays each received 20-30 million fish (Table 1). However, at least 1.8 million fish were stocked into remaining bay systems except Sabine Lake and East Matagorda Bay. Red drum was the major species stocked.

Striped bass, spotted seatrout, black drum, and snook (Centropomus undecimalis) were also stocked. Red drum stocked prior to 1983 were mainly fry; fingerlings were almost exclusively stocked thereafter (Table 2). Striped bass fingerlings were stocked to examine the feasibility of establishing a fishery in the San Antonio and Corpus Christi Bay systems in the 1970's (Table 3). Matlock et al. (1984) concluded this effort was unsuccessful for unknown reasons. A 5-year stocking program was initiated in 1983 to re-establish the striped bass fishery in the Galveston Bay system using fry. About 1,000,000 fry have been stocked each year (Table 3). Over 1 million spotted seatrout fry and fingerlings have also been stocked in the Matagorda Bay System since 1983 (Table 4). All spotted seatrout produced during spawning and culture experiments at the Perry R. Bass Marine Fisheries Research Station and were placed into Matagorda Bay. Black drum fingerlings reared at the same station as part of a hybrid study were placed into the San

Antonio Bay system on 8 May 1984 (31,000 fish; 25-38 mm) and into the Matagorda Bay system on 17 November 1984 (4,249 fish; 150 mm).

On 29 October 1985, 261 tagged snook fingerlings (90-109 mm) were stocked into the Aransas Bay system in Port Bay. These fish were obtained as eggs from the Florida Department of Natural Resources, reared in earth ponds at the Perry R. Bass Marine Fisheries Research Station, and tagged with internal abdominal tags with external streamers before release. Few, if any, of these fish survived stocking. Handling mortality was extremely high; 1282 of 1615 fish died during transport to the stocking site. Twenty-five fish were held in each of four cages at the stocking site for 48 hours. Survival after 24 hours was 48, 52, 60, and 84%, but by 48 hours survival was 24, 36, 24, and 28%, respectively. No snook were captured in bag seines pulled at the stocking sites and two nearby sites (within 800 m) on 5 and 19 November and 3 December 1985.
